# 5.1 Contour-based techniques for image segmentation

Image segmentation is the process of **assigning a label to every pixel in an image** such that pixels with the same label share certain characteristics. As a consequence, it produces regions whose pixels have similar properties (*e.g.* intensity, color, texture, or location in the image) which have a geometric and semantic meaning (see Fig.1). The result of image segmentation could be:

- · a set of segments that collectively cover the entire image (e.g. thresholding),
- or a set of contours extracted from the image (e.g. edge detection).

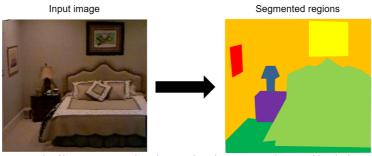

Fig. 1: Example of image segmentation where each region corresponds to an object in the scene.

Conceptually, two traditional approaches to image segmentation exist (see Fig. 2):

- Top-down segmentation (semantic segmentation), which considers that pixels from the same object in the scene should be in the same segmented region.
- Bottom-up segmentation (pixel-driven segmentation), which establishes that similar pixels in the image must be in the same segmented region.

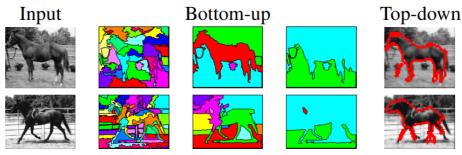

Fig. 2. An example of top-down and bottom-up approaches. Adopted from [1] (myfootnote1)

We put the spotlight here on bottom-up segmentation approaches. Methods following such approach can be grouped into:

- Contour-based techniques, which attempt to identify the image regions by detecting their contours.
- Region-based techniques that group together pixels that are similar.

In this book we are going to experience both, starting with **contour-based techniques**, whose are based on detecting specific contours in the image (e.g. circles). In this context, image contours are defined as edge pixels that enclose a region.

Contour-based techniques could be roughly classified into:

- Local tecniques. Try to segment regions by detecting closed contours, which typically enclose pixels with similar intensities.
  - LoG + zero crossing.
  - Edge following (Canny operator).
- Global techniques. Detect particular shapes in the image (circles, lines, etc.).
  - Hough transform.

This notebook will cover the Hough transform (section 5.1.1), a contour-based technique that can be used for detecting regions with an arbitrary shape in images.

# **Problem context - Self-driving car**

A prestigious company located at PTA (The Andalusia Technology Park) is organizing a <u>hackathon (https://en.wikipedia.org/wiki/Hackathon)</u> for this year in order to motivate college students to make further progress in the autonomous cars field. Computer vision students at UMA decided to take part in it, but the organizers have posed an initial basic task to guarantee that participants have expertise in image processing techniques.

This way, the company sent to students a task for **implementing a basic detector of road lane lines using OpenCV in python**. We are lucky! These are two tools that we know well ;).

Detecting lines in a lane is a fundamental task for autonomous vehicles while driving on the road. It is the building block to other path planning and control actions like breaking and steering.

So here we are! We are going to detect road lane lines using Hough transform in OpenCV.

```
In [1]: import numpy as np
import cv2
import math
import matplotlib.pyplot as plt
import matplotlib
import scipy.stats as stats

matplotlib.rcParams['figure.figsize'] = (10.0, 10.0)
images_path = './images/'
```

# 5.1.1 Hough transform

The Hough Transform is a technique for the detection of arbitrary shapes in an image. For that, such shapes must be expressed in:

- analytical form (classic Hough), e.g. using the mathematical representation of lines, circles, ellipses, etc., or
- in a numerical form (generalized Hough) where the shape is given by a table.

Since our goal is to detect lines, we will focus here on analytically expressed shapes. Specifically, a line can be represented analytically as:

$$y = mx + n$$

or in its parametric form, as:

Hello world

$$\rho = x \cos \theta + y \sin \theta$$

where  $\rho$  is the perpendicular distance from the origin (0,0) to the line, and  $\theta$  is the angle formed by this perpendicular line and the horizontal axis measured in counter-clockwise (see Fig. 3). Thereby, we are going to represent lines using the pair of parameters  $(\rho,\theta)$ .

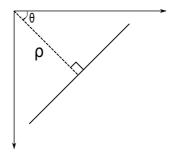

Fig. 3. Parametric representation of a line.

The Hough transform works by a voting procedure, which is carried out in a parameter space ( $\rho$ ,  $\theta$  in our case). This technique consists of the following steps:

1. **Build an accumulator matrix**, where rows index the possible values of  $\rho$ , and columns those for  $\theta$ . For example, if the possible values for  $\rho$  are  $0, 1, 2, \dots d$  (where d is the max distance e.g. diagonal size of the image) and those for  $\theta$  are  $0, 1, 2 \dots 179$ , the matrix shape would be (d, 180).

```
In [2]: # Define possible rho and theta values
    theta_values = [0,np.pi/4,np.pi/2,3*np.pi/4]
    rho_values = [0,1,2,3,4,5]

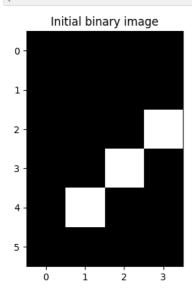

# Create the accumulator
    acc = np.zeros([len(rho_values),len(theta_values)])
    print(acc) # auxiliar mio

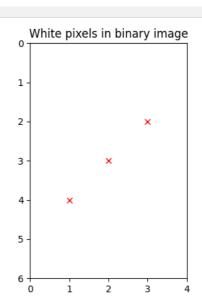

print("Hello world")

[[0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
    [0. 0. 0. 0.]
```

2. Binarize the input image to obtain pixels that are candidates to belong to the shape contours (e.g. by applying an edge detector).

```
In [3]: # Coordinates of white points in binary image
         xs = np.array([1,2,3])
         ys = np.array([4,3,2])
         # Initial image
         plt.subplot(221)
         blank_image = np.zeros((6,4,1), np.uint8)
blank_image[ys,xs] = 255 # asigna valores blancos en las posiciones determinadas por los arrays predefinidos anteriormente
         plt.imshow(blank_image, cmap='gray');
         plt.title('Initial binary image')
         # Show them!
         plt.subplot(222)
         plt.plot(xs,ys,'rx')
plt.axis('scaled')
         axes = plt.gca()
         axes.set_xlim([0,4])
         axes.set_ylim([0,6])
         plt.gca().invert_yaxis()
         plt.title('White pixels in binary image');
```

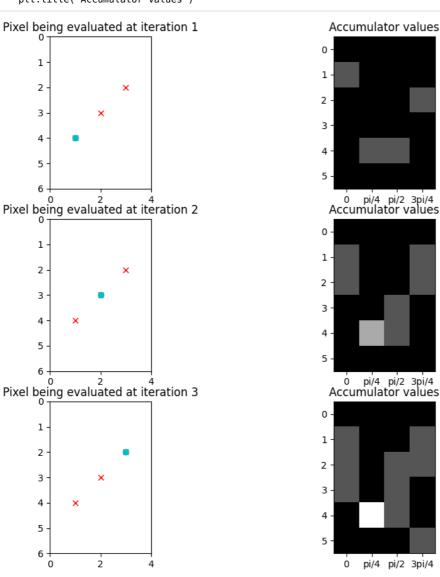

- 3. For each candidate (white pixel):
  - A. **Evaluate**: Since the point coordinates (x,y) are known, place them in the line parametric form and iterate over the possible values of  $\theta$  to obtain the values for  $\rho$ . In the previous example  $\rho_i = x \cos \theta_i + y \sin \theta_i$ ,  $\forall i \in [0,180]$
  - B. **Vote**: For every obtained pair  $(\rho_i, \theta_i)$  increment by one the value of its associated cell in the accumulator.

If we do this with an accumulator with an enough resolution, we would get a sinusoid.

```
In [4]: # For each white pixel
        for i in range (0,len(xs)):
            x = xs[i]
            y = ys[i]
            # Show the point voting
            subplot index = str(32) + str(i*2+1)
            plt.subplot(int(subplot_index))
            plt.axis('scaled')
            axes = plt.gca()
             axes.set_xlim([0,4])
            axes.set_ylim([0,6])
            plt.plot(xs,ys,'rx')
            plt.plot(x,y,'co')
            plt.title('Pixel being evaluated at iteration ' + str(i+1))
            plt.gca().invert_yaxis()
             # Ecaluate the (x,y) coordinates for different values of theta, and
             # retrieve rho
             for theta_index in range(0,len(theta_values)):
                 theta = theta_values[theta_index]
                 rho = x*np.cos(theta) + y*np.sin(theta)
                 rho = int(np.round(rho))
                 # Vote!
                 acc[rho][theta\_index] += 1.0
             # Show the acccumulator
            subplot_index = str(32) + str(i*2+2)
            plt.subplot(int(subplot_index))
            plt.imshow(acc,cmap='gray',vmax=3);
plt.xticks([0, 1, 2, 3], ['0','pi/4','pi/2','3pi/4'])
            plt.title('Accumulator values')
```

<sup>4.</sup> Finally, **obtain the shape candidates** by setting a threshold to control how many votes needs a pair  $(\rho, \theta)$  to be considered a line, and by applying local maxima in the accumulator space.

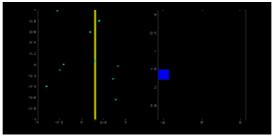

Fig. 3. Left, image space. Right, parameter space illustrating the evolution of the votes. Note that in this example  $\theta$  have only 8 possible values.

The idea behind this algorithm is that when a pixel in the image space votes for all the lines that go through it in the parameter space, when a second pixel belonging

#### OpenCV pill

OpenCV implements the method <a href="cv2.HoughLines()">cv2.HoughLines()</a>

(https://docs.opencv.org/4.2.0/dd/d1a/group imgproc feature.html#ga46b4e588934f6c8dfd509cc6e0e4545a) for detecting lines using the Hough transform. However, prior to its usage, and as commented in the step 1. of the algorithm, it is needed a binary image. For that we are going to resort to our old friend the Canny algorithm, so the detected edges will be the white pixes in the binary image.

As we now, noisy images seriously hamper the performance of computer vision techniques, and since cv2.Canny()

(https://docs.opencv.org/4.2.0/dd/d1a/group imgproc feature.html#ga04723e007ed888ddf11d9ba04e2232de) does not include blurring, we provide here a method called gaussian smoothing() to assist you in that task.

```
In [5]: def gaussian_smoothing(image, sigma, w_kernel):
              "" Blur and normalize input image.
                Args:
                    image: Input image to be binarized
                    sigma: Standard deviation of the Gaussian distribution
                    w_kernel: Kernel aperture size
                Returns:
                    binarized: Blurred image
            # Define 1D kernel
            s=sigma
            w=w kernel
            kernel_1D = [np.exp(-z*z/(2*s*s))/np.sqrt(2*np.pi*s*s)  for z in range(-w,w+1)]
            # Apply distributive property of convolution
            kernel 2D = np.outer(kernel 1D,kernel 1D)
            # Blur image
            smoothed_img = cv2.filter2D(image,cv2.CV_8U,kernel_2D)
            # Normalize to [0 254] values
            smoothed_norm = np.array(image.shape)
            smoothed_norm = cv2.normalize(smoothed_img,None, 0, 255, cv2.NORM_MINMAX)
            return smoothed norm
```

#### ASSIGNMENT 1: Detecting lines with Hough

Your first task is to apply <a href="mailto:cv2.HoughLines()">cv2.HoughLines()</a> (<a href="https://docs.opencv.org/4.2.0/dd/d1a/group\_imgproc\_feature.html#ga46b4e588934f6c8dfd509cc6e0e4545a">https://docs.opencv.org/4.2.0/dd/d1a/group\_imgproc\_feature.html#ga46b4e588934f6c8dfd509cc6e0e4545a</a>) to the image <a href="car.org/a.2.0/de/de6e0e4545a">car.org/a.2.0/de/de6e0e4545a</a>) to the image <a href="car.org/a.2.0/de/de6e0e4545a">car.org/a.2.0/de6/de6e0e4545a</a>) to the image <a href="car.org/a.2.0/de6/de6e0e4545a">car.org/a.2.0/de6/de6e0e4545a</a>) to the image <a href="car.org/a.2.0/de6/de6e0e4545a">car.org/a.2.0/de6/de6e0e4545a</a>) to the image <a href="car.org/a.2.0/de6/de6e0e4545a">car.org/a.2.0/de6/de6e0e4545a</a>) in the image <a href="car.org/a.2.0/de6/de6e0e4545a">car.org/a.2.0/de6/de6e0e45a</a>) in the image <a href="car.org/a.2.0/de6/de6e0e45a</a>) in the image <a

The main inputs of  $\ensuremath{\text{cv2.HoughLines()}}$  are:

- image: binary input image
- rho: distance resolution of the accumulator in pixels (usually 1, it may be bigger for high resolution images)
- theta: angle resolution of the accumulator in radians. (usually  $\frac{\pi}{180}$ )
- threshold: only line candidates having a number of votes > threshold are returned.

And it returns:

• a  $(n\_linesx1x2)$  array containing, in each row, the parameters of each detected line in the  $[\rho,\theta]$  format.

Note that, for drawing the lines, you have to <u>transform the resultant lines (https://answers.opencv.org/question/21132/draw-the-lines-detected-by-cvhoughlines/)</u> from the  $(\rho, \theta)$  space to Cartesian coordinates.

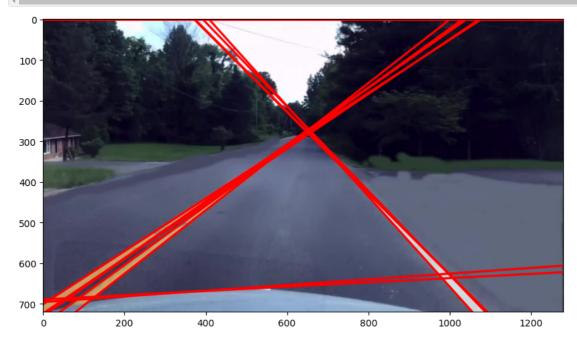

Try different parameter values until you get something like this:

```
0 -
100 -
200 -
```

```
In [8]: # Assignment 1
         # Read the image
         image = cv2.imread(images_path + "car.png",-1)
         # Convert to RGB and get gray image
         image = cv2.cvtColor(image, cv2.COLOR_BGR2RGB)
         gray = cv2.cvtColor(image, cv2.COLOR_BGR2GRAY)
         # Blur the gray image
         gray = gaussian_smoothing(gray,2,5)
         # Apply Canny algorithm
         edges = cv2.Canny(gray,100,120,apertureSize = 3) # no sabemos por que con 200 como tercer parametro no detecta una de las
         # Search for lines using Hough transform
         lines = cv2.HoughLines(edges, rho=1, theta=np.pi/180, threshold=150)
         # For each line
         for i in range(0, len(lines)):
             # Transform from polar coordinates to cartesian coordinates
             rho = lines[i][0][0]
             theta = lines[i][0][1]
             a = math.cos(theta)
             b = math.sin(theta)
             x0 = a * rho
             y0 = b * rho
             # Get two points in that line
             x1 = int(x0 + 2000*(-b));

y1 = int(y0 + 2000*(a))
             pt1 = (x1, y1)
             x2 = int(x0 - 2000*(-b))

y2 = int(y0 - 2000*(a))
             pt2 = (x2, y2)
             # Draw the line in the RGB image
             cv2.line(image, pt1, pt2, (255,0,0), 3, cv2.LINE_AA)
         # Show resultant image
         plt.imshow(image);
```

### 5.1.2.1 Probabilistic Hough transform

For high-resolution images and large accumulator sizes the Hough transform may need long execution times. However, in applications like autonomous cars a fast execution is mandatory. For example, having a car moving at 100 km/h covers  $\sim 28$  meters in a second. Imagine how much lines can change in that time!

OpenCV provides with the method <a href="cv2.HoughLinesP(">cv2.HoughLinesP()</a>)

(https://docs.opencv.org/4.2.0/dd/d1a/group imgproc feature.html#ga8618180a5948286384e3b7ca02f6feeb), a more complex implementation of the Hough Line Transform, which is called **probabilistic Hough Transform**. This alternative does not take all the points in the binary image into account, but a random subset of them that are still enough for line detection. This also results in lower thresholds when deciding if a line exists or not.

#### ASSIGNMENT 2: Another option for detecting lines

 $\label{eq:condition} \begin{aligned} & \text{Apply } \underline{\text{cv2.HoughLinesP()}} \ \, \underline{\text{(https://docs.opencv.org/4.2.0/dd/d1a/group imgproc}} \ \, \underline{\text{feature.html}\#\text{ga8618180a5948286384e3b7ca02f6feeb)}} \ \, \text{to the image car.png} \ \, \text{and draw the detected lines.} \end{aligned}$ 

This function returns:

• line segments [x1,y1,x2,y2] instead of the line equation parameters.

For that, two additional arguments are needed:

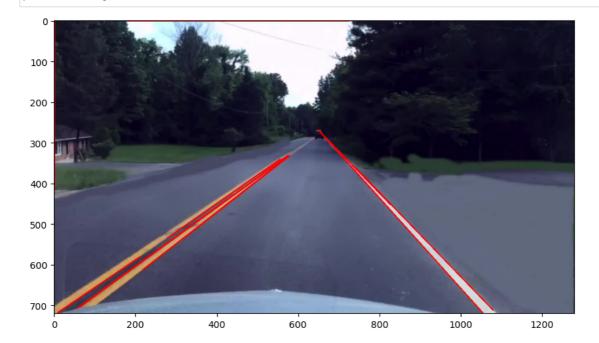

- $\bullet\,$  minLineLength: line segments shorter than that are rejected.
- maxLineGap: maximum allowed gap between points on the same line to link them.

Try different parameter values until you get something like this:

Fig. 5. Lines detection example with the probabilistic Hough Transform.

```
In [9]: # Assignent 2
        # Read the image
        image = cv2.imread(images_path + "car.png",-1)
        # Convert to RGB and get gray image
        image = cv2.cvtColor(image, cv2.COLOR_BGR2RGB)
        gray = cv2.cvtColor(image, cv2.COLOR_RGB2GRAY)
        # Blur the gray image
        gray = gaussian_smoothing(gray,1,2)
        # Apply Canny algorithm
        edges = cv2.Canny(gray,100,200,apertureSize = 3)
        # Search for lines using probabilistic Hough transform
        rho = 1
        theta = np.pi/180
        threshold = 220
        lines = cv2.HoughLinesP(edges, rho, theta, threshold,
                                minLineLength=10, maxLineGap=40)
        # For each line
        for line in lines:
            # Draw the line in the RGB image
            x1,y1,x2,y2 = line[0]
            cv2.line(image,(x1,y1),(x2,y2),(255,0,0),2)
        # Show resultant image
        plt.imshow(image);
```

## Thinking about it (1)

Now that you have played with the Hough Transform, answer the following questions:

- In the first assignment, we obtained an image with a number of red lines drawn on it. However, these lines goes over pixels in the image that do not contains lines! (e.g. belonging to the sky). What could we do to fix this, that is, obtain the pixels belonging to lines in the image?
  - Podríamos llevarlo a cabo mediante 2 métodos distintos. El primero de ellos, mucho menos resolutivo sería dejar de trazar las líneas de las rectas a partir de que 2 de ellos se cortase, de modo que evitariamos que en el cielo la recta continuara dibujada (aunque en el capo del coche el problema seguiría). Por otro lado, podríamos hacer que solo se dibujase aquellas rectas que coincidieran con bordes detectados por Canny.
- Without restrictions regarding execution time, which method would you use, Hough Transform or its probabilistic counterpart?
  - En este ejemplo en concreto considero que sería mejor usar Hough en el caso que averiguaramos una manera de limitar las rectas "infinitas" dibujadas en la imagen, ya que el algoritmo que usa probabilidades está abierto a cometer algún fallo y no tener en cuenta alguna recta que realmente si lo era en la imagen original.
- Could there be a cell in the accumulator with a value higher than the number of white pixels in the binary image? why?
  - Podría llegar a darse, pero si una celda en el acumulador tiene un valor más alto que el número de píxeles blancos en la imagen binaria, significaría que hay más líneas estimadas que píxeles en la imagen. Esto sería una situación poco realista y poco probable, ya que normalmente se espera que las líneas detectadas no sean más numerosas que los píxeles en la imagen.
- Which should be the maximum value for  $\rho$  in the accumulator? Why?
  - Dependerá de la imagen que estemos analizando, ya que cada imagen presenta unas dimensiones, y por consiguiente su diagonal (que es la variable o magnitud que determina dicho maximo) varía.

# **OPTIONAL**

Think about any other application where the finding of straight lines could be useful. Get some images related to said application and detect lines with the Hough transform!

# Conclusion

Terrific work! In the road lane lines detection context you have learned:

 $\bullet\,$  to detect shapes in images using Hough transform .

Also, you obtained some knowledge about:

- self-driving cars and computer vision, and
- lane line detection for autonomous cars.

See you in the next one! Keep learning!
